э

メロト メポト メヨト メヨト

- Government Gazettes are a great source of information of public interest:
 - Nominations, contracts, public notices.
 - Public expenditures may be subject to frauds and irregularities.
- Difficulties:
 - Unstructured data.
 - Domain-specific language (official texts).

Examples

Excerpt 1

O GOVERNADOR DO DISTRITO FEDERAL, no uso das atribuições que lhe confere o artigo 100, incisos XXVI e XXVII, da Lei Orgânica do Distrito Federal, resolve [...]

Excerpt 2

Presidente da COVED, acolhendo os pareceres inseridos nos processos abaixo, declara habilitados para a venda à PRAZO os itens a seguir: [...]

Excerpt 2

[...] TORNAR PÚBLICO o resultado das investigações constantes nos processos dos servidores listados abaixo e que se configuraram em acidente de serviço, sem dano, nos termos do artigo 23, \S 1°, inciso IV, do Decreto n° 34.023, de 10 de dezembro de 2012, observando-se a seguinte ordem: número do processo, nome e matrícula. [...]

- Identify the public body of origin of documents fom the Official Gazette of the Federal District through Machine Learning.
 - First step in the direction of structuring the information present in Official Gazettes.
 - Extracting the public entity that produced the document by using rules and regular expressions is not robust.
- Leverage unlabelled samples through transfer learning (ULMFiT [Howard and Ruder, 2018]) to compensate for the small number of annotated instances.

(4) (日本)

- Making available to the community a dataset with labelled and unlabelled Official Gazette documents.
- Training, evaluating and comparing a ULMFiT model to traditional bag-of-words models.
- Performing an ablation analysis to examine the impact of the ULMFiT steps when trained on our data.

The dataset

Teófilo E. de Campos (UnB)

Inferring the source of official texts

February 14, 2020 8 / 36

2

メロト メポト メヨト メヨト

- 2,652 texts extracted from the Official Gazette of the Federal District.¹
- Handcrafted regex rules to extract some information from each sample: publication date, section number, public body that issued the document, title and others.
- 797 texts manually examined: 724 free of labelling mistakes.

- Documents originated from 25 different public entities.
- Filter out entities with less than three samples.
 - Final count: 717 labelled examples from 19 different public entities.
- Divide the data into two separate parts:
 - ▶ 717 labelled examples for public entity of origin classification.
 - 1,928 unverified or incorrectly labelled samples for unsupervised training of a language model.

¹Available at https://www.dodf.df.gov.br/.

Inferring the source of official texts

- Randomly sample 8/15 (384) of the texts for the training set, 2/15 (96) for the validation set and 5/15 (237) for the test set.
- Imbalanced data: most frequent class (*Segurança Pública*) with 140 samples and least frequent classes with less than 5 documents.

Data Distribution

Classes Distribution

э

- Drop two empty texts, totalizing 1,926 documents.
- 80 % for training and 20 % for validation.
 - ► No test set: no need for unbiased evaluation of the language model.
- Total of 984,580 tokens: 784,260 in the training set and 200,320 in the validation set.
- Standard language modelling task: label of each token is the following token in the sentence.

The models

Teófilo E. de Campos (UnB)

Inferring the source of official texts

February 14, 2020 14 / 36

3

・ロト ・ 日 ト ・ 日 ト ・ 日 ト

- Lowercase text and use SentencePiece [Kudo and Richardson, 2018] to tokenize.
 - The same used for the pretrained language model.
- Add special tokens for padding, first letter capitalization, all letters capitalization, character and word repetition etc.²
- Final vocabulary of 8,552 tokens, including words, subwords, special tokens and punctuation.

²List of special tokens used available at https://docs.fast.ai/text.transform.html

Teófilo E. de Campos (UnB)

Inferring the source of official texts

- Two kinds of BOW:
 - tf-idf values;
 - token counts.
- Two classifiers:
 - Naïve Bayes (NB);
 - Support Vector Machines (SVM) with linear kernel.

э

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

- Language Model Fine-Tuning (ULMFiT) [Howard and Ruder, 2018] to leverage information contained in the unlabeled language model dataset. Three stages:
- Language model pre-training: we use a bidirectional Portuguese language model³ trained on 166,580 Wikipedia articles (100,255,322 tokens).
 - Architecture: 400-dimensional embedding layer + 4 Quasi-Recurrent Neural Network (QRNN [Bradbury et al., 2016]) layers + linear classifier.

Transfer learning II

- Language model fine-tuning: we fine-tune the forward and backward pre-trained language models on our unlabelled dataset.
 - We use discriminative fine-tuning (different learning rates for different layers) and cyclical learning rates [Smith and Topin, 2017] with cosine annealing to speed up training.

Transfer learning III

- Classifier fine-tuning: we add two linear blocks to the language models (batch normalization [loffe and Szegedy, 2015] + dropout [Srivastava et al., 2014] + FC layer).
 - > Final prediction is the average of the forward and backward models.
 - Let h_t be the hidden state of the last time step, and
 H = {h_{t−T}, · · · , h_t}, be the hidden states of as many time steps as can be fit in GPU memory. Then, the input to the linear blocks h_c is:

$$\mathbf{h}_{c} = \operatorname{concat}(\mathbf{h}_{t}, \operatorname{maxpool}(\mathbf{H}), \operatorname{averagepool}(\mathbf{H})). \tag{1}$$

Experiments

20 / 36

・ロト ・ 日 ト ・ 日 ト ・ 日 ト

- Random search + evaluation on validation set to find best hyperparameter values.
- Four scenarios: tf-idf + NB; tf-idf + SVM; counts + NB; counts + SVM.
- For each scenario we train 100 models with different randomly assigned hyperparameter values.

E 6 4 E 6

Baseline II

- Vectorizers hyperparameters:
 - n-gram range (only unigrams, unigrams and bigrams, unigrams to trigrams).
 - maximum document frequency (50%, 80% and 100%)
 - minimum number of documents (1, 2 and 3 documents)
- NB hyperparameters:
 - Smoothing prior α uniformly sampled from {0.0001, 0.0003, 0.001, 0.003, 0.01, 0.03, 0.1, 0.3, 1}.
 - Fitting prior probability vs. using uniform prior distribution.
- SVM hyperparameters:
 - Regularization parameter C sampled from {0.001, 0.003, 0.01, 0.03, 0.1, 0.3, 1, 3, 10}
 - Applying weights inversely proportional to class frequencies vs. unitary weight for all classes.

22 / 36

Transfer learning I

- We use the learning rate range test [Smith, 2015] to tune the learning rate.
- Adam is used as the optimizer.
- Language model fine-tuning:
 - We fine-tune the top layer of the forward and backward language models for one cycle of two epochs and then train all layers for one cycle of ten epochs.
 - Batch size of 32 documents, weight decay of 0.1, BPTT of length 70 and dropout probabilities of 0.1, 0.6, 0.5 and 0.2 applied to embeddings inputs, embedding outputs, QRNN hidden-to-hidden weight matrix and QRNN output, respectively.

4 AR & 4 E & 4 E &

• Classifier fine-tuning:

- We employ gradual unfreezing to prevent catastrophic forgetting:
 - We unfreeze one layer at a time, starting from the last, each time fine-tuning for one cycle of 10 epochs.
- Batch size of 8 documents, weight decay of 0.3, BPTT of length 70 and the same dropout probabilities used for the language model fine-tuning scaled by a factor of 0.5.

2

< □ > < □ > < □ > < □ > < □ >

26 / 36

- All models performed better than a majority class classifier, which wields F₁ scores of 7.35 and 1.83 and an accuracy of 21.10.
- The SVM and ULMFiT models outperformed the Naive Bayes classifier across almost all categories.
- F₁ scores and accuracies approaching 90.00% indicate good results, though we do not have a human performance benchmark for comparison.

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

Results III

- SVM and ULMFiT scores are comparable: the former has greater average F₁ score while the latter wins at weighted F₁ score and accuracy.
- SVM has some advantages:
 - Time: SVM takes less than two seconds to train on CPU, while ULMFiT takes more than half an hour on GPU.
 - Simplicity: SVM training is straightforward, while ULMFiT requires three different steps with many parts that need tweaking (gradual unfreezing, learning rate schedule, discriminative fine-tuning).
- Consequence: ULMFiT has more hyperparameters to tune and each search iterations is expensive—the time it takes to train one ULMFiT model is enough to train more than 1,000 SVM models with different configurations of hyper-parameters.

28 / 36

・ 同 ト ・ ヨ ト ・ ヨ ト

- Four scenarios using the same hyperparameters and trained for the same number of iterations:
 - ▶ No gradual unfreezing: we fine-tune all layers at the same time.
 - ► Last layer fine-tuning:we treat language model as feature extractor and fine-tune only the linear blocks on top (classifier).
 - No language model fine-tuning: we skip the language model fine-tuning and train the classifier directly from the pretrained language model, using gradual unfreezing.
 - Direct transfer: similar to the previous step, though we train all layers at the same time instead of employing gradual unfreezing.

- 4 回 ト 4 三 ト 4 三 ト

Ablation analysis II

Table: Ablation scenarios results (in %) on the test set.

Model	Average F1	Weighted F1	Accuracy
No gradual unfreeezing (f)	82.34 (-0.32)	89.46 (+2.00)	89.87 (+2.11)
No gradual unfreeezing (b)	80.8 (+1.32)	89.07 (+9.03)	89.87 (+0.84)
No gradual unfreeezing (f+b)	82.76 (-1.93)	89.66 (- 0.08)	89.87 (-0.43)
Last layer fine-tuning (f)	63.30 (-19.36)	77.39 (-10.07)	78.90 (-8.86)
Last layer fine-tuning (b)	60.48 (-19.00)	77.03 (-11.11)	78.48 (-10.55)
Last layer fine-tuning (f+b)	66.37 (-18.32)	79.60 (-10.14)	81.01 (-9.29)
No LM fine-tuning (f)	28.05 (-54.61)	47.24 (-40.22)	53.59 (-34.17)
No LM fine-tuning (b)	27.32 (-52.16)	39.24 (-48.90)	50.63 (-38.40)
No LM fine-tuning (f+b)	31.48 (-53.21)	46.06 (-43.68)	55.27 (-35.03)
Direct transfer (f)	11.78 (-70.88)	24.33 (-63.13)	32.07 (-55.69)
Direct transfer (b)	8.33 (-71.15)	14.01 (-74.13)	27.85 (-61.18)
Direct transfer (f+b)	11.54 (-73.15)	24.00 (-65.74)	34.60 (-55.70)

・ロト ・ 日 ト ・ 日 ト ・ 日 ト

Conclusion

- We have compared the performance of ULMFiT and BOW methods when identifying the public entity that originated Official Gazette texts.
- We have performed an analysis to identify the impact of gradual unfreezing, language model fine-tuning and the use of the fine-tuned language model as a text feature extractor.
- We have found that SVM is competitive with ULMFiT, a SOTA technique, when considering its simpler training procedure, parameter tuning and faster training time.
- The ablation analysis indicate the combination of LM tuning and gradual unfreezing is beneficial. On the other hand, LMs, even fine-tuned on domain data, are not good feature extractors.
